- Q4. From your results, what proportion of the original variance is captured by the first principal components (PC1)? 44.27%
- Q5. How many principal components (PCs) are required to describe at least 70% of the original variance in the data? The first 3 PCs are required
- Q6. How many principal components (PCs) are required to describe at least 90% of the original variance in the data? The first 7 PCs are required

#### biplot(wisc.pr)

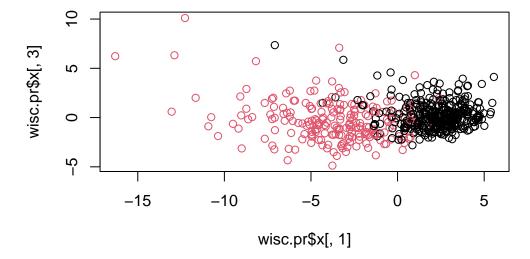

Q7. What stands out to you about this plot? Is it easy or difficult to understand? Why? This

plot is very complicated and cluttered. It is almost impossible to read and nearly nothing can be understood from it.

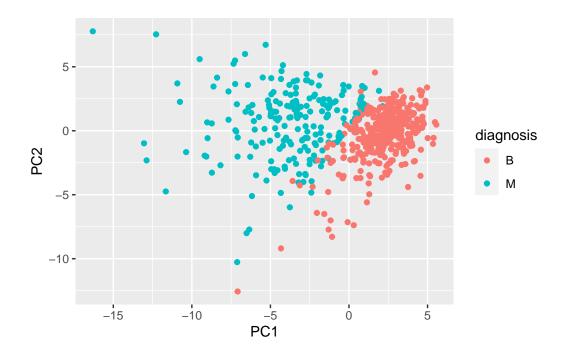

Q8. Generate a similar plot for principal components 1 and 3. What do you notice about these plots? The malignant and benign patients are cluttered separate from each other.

Q9. For the first principal component, what is the component of the loading vector (i.e. wisc.pr\$rotation[,1]) for the feature concave.points\_mean?

```
wisc.pr$rotation[,1]["concave.points_mean"]
```

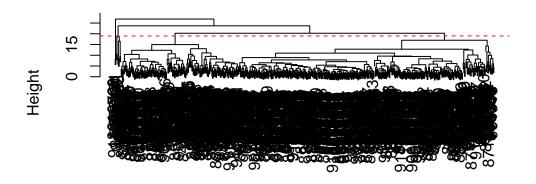

```

Q11.Using the plot() and abline() functions, what is the height at which the clustering model has 4 clusters? At around height 19

```

Q12. Can you find a better cluster vs diagnoses match by cutting into a different number of clusters between 2 and 10? No, k=4 has the best cluster vs diagnoses match as it maximizes the separation between malignant and benign cells the best.

Q13. Which method gives your favorite results for the same data.dist dataset? Explain your reasoning. Ward.d2 gives my favorite results for the dataset because there is a clear distinction between benign and malignant cells, and it is overall much easier to analyze.

Q15. How well does the newly created model with four clusters separate out the two diagnoses? It does a great job, the separation between malignant and benign cell is well optimized.
